Data Report 88/1

PREFACE

The Data Report Series is intended as a readily available source of basic data collected for lakes and watersheds in the Muskoka/ Haliburton area of Ontario. These data were collected as part of the Lakeshore Capacity Study and/or the Acid Precipitation in Ontario Study.

The limnological portion of the Lakeshore Capacity Study (1975-81) was initiated to investigate the relationships between lakeshore development and trophic status in low ionic strength Precambrian lakes. The Acid Precipitation in Ontario Study (1979 - present) was initiated, in part, to investigate the effects of the deposition of strong acids on aquatic and terrestrial ecosystems in Ontario. The primary findings of these studies have been and will continue to be published as reviewed papers and technical reports.

ABSTRACT

This progress report summarizes the 1986 lake chemistry data for Lake Muskoka, Lake Joseph, Lake Rosseau and Lake of Bays. The nutrient levels show that the lakes are oligotrophic. The alkalinity data indicates the lakes are moderately sensitive to acidic deposition. A comparison of the volume weighted and tube composite sampling methodology indicates that these two methods are comparable.

Reid, R. A. and R. Girard, 1987. *Muskoka Lakes Project: A Progress Report of the 1986 data.* Ontario Ministry of the Environment Data Report. DR 88/1.

SOMMAIRE

Le présent rapport résume les données recueillies en 1986 sur les caractéristiques chimiques du lac Muskoka, du lac Joseph, du lac Rosseau et du Lake of Bays. D'après leur charge nutritive, ces lacs sont oligotrophes, et leur alcalinité révèle qu'ils sont plus ou moins sensibles aux dépôts acides. Par ailleurs, l'examen des méthodes d'échantillonnage (l'une à volume simple, l'autre à volume composé) indique que les deux méthodes sont comparables.

EXECUTIVE SUMMARY

This report summarizes the progress of the Muskoka Lakes project which began in 1986.As part of the Inland Lakes programme, the Muskoka Lakes project is monitoring the impact of acid deposition and localized nutrient loading on the water quality of Muskoka's four largest lakes:

- Lake Muskoka
- Lake Joseph
- Lake Rosseau
- Lake of Bays
    - each lake had several sampling locations - Lake Muskoka (13), Lake Joseph (11), Lake Rosseau (12) and Lake of Bays (12) for a total of 48 sampling sites.
    - each site was sampled monthly except Gravenhurst Bay (GB) and Muskoka Bay (MB) on Lake Muskoka which were sampled bi-weekly.
    - this is a report on the first of three years of monitoring. A more complete report will be published after three years.

Findings:

Chemistry data

- low levels of nutrients and chlorophyll in the study lakes indicate little enrichment. The chemistry data indicates only small differences among sampling sites on each lake.

Table 1. Mean values and standard deviation for nutrients and chlorophyll ($\mu g \cdot L^{-1}$) during the ice-free season for the four study lakes in 1986.

Lake	TP (Total Phosphorus)	NH_4 Ammonium	NO_3 Nitrate	Total Kjeldahl Nitrogen	Chl-a
Lake Muskoka	5.30 (1.92)	9.9 (3.8)	213.1 (24.9)	210.2 (17.8)	1.52 (0.26)
Lake Rosseau	4.48 (1.02)	8.6 (3.2)	190.1 (21.3)	190.9 (23.9)	1.40 (0.32)
Lake Joseph	3.22 (0.63)	9.1 (3.9)	117.2 (12.9)	170.0 (29.0)	1.92 (0.55)
Lake of Bays	3.83 (0.71)	9.6 (4.9)	131.9 (27.6)	179.5 (26.4)	1.67 (0.35)

- each lake is rated moderately sensitive to acid deposition based on the alkalinity values of 63-93 µeq•L^{-1} as $CaCO_3$.

Alkalinity (µeq•L^{-1} as $CaCO_3$)			
	Mean	S.D.	
Lake Muskoka	92.7	(8.6)	(excludes GB and MB)
Lake Rosseau	87.9	(3.8)	
Lake Joseph	63.1	(3.6)	
Lake of Bays	70.9	(5.6)	

- hypolimnetic oxygen levels were <5 mg•L^{-1} at 10 of the 48 stations during the late summer of 1986.

- localized nutrient enrichment occurs in Gravenhurst Bay and Muskoka Bay because of loadings into these bays from the Gravenhurst Sewage Treatment Plant.

	Total Phosphorus	Total Kjeldahl Nitrogen	Chl-a	Secchi Depth
	- - - - - - - - µg•L^{-1} - - - - -			m
Gravenhurst Bay	9.9	320	4.5	3.8
Muskoka Bay Lake	9.3	291	4.3	3.6
Muskoka (11 stations)	5.3	210	1.5	5.1

- filamentous algae (*Zygnema*, sp.) occurred on Trading Bay, Rabbit Bay and Pancake Bay (Lake of Bays) in August 1986 (M. Jackson - unpub. data and O.M.E., 1986). No significant growth occurred in any other areas of the lakes. The presence of this particular filamentous algae is often considered as an early indicator of acidification.

- the comparison of the volume-weighted and tube composite sampling methodology showed no significant differences.

RECOMMENDATIONS

- reduce the number of sampling stations on the four lakes from 48 to 26 (Figure 1-4, Appendix 1 and Figures 5-8, Appendix 4) to focus on the embayments.

- sample for dissolved oxygen only at the 10 sites which showed a hypolimnetic depletion in 1986

- monitor all 48 stations every three to five years

- sample Gravenhurst and Muskoka Bay bi-weekly by the Volume-weighed Sampling Methodology

- map the occurrence of the filamentous algae annually.

INTRODUCTION

The Muskoka Lakes Monitoring Project began in 1986. The objectives are to:

- assess the degree of enrichment of Lakes Muskoka, Joseph, Rosseau and Lake of Bays with emphasis on the embayments;
- compare the 1986 results with those of previous surveys and to determine if there has been any significant change in water quality;
- update the acid sensitivity assessment for Lake of Bays;
- document the occurrence and distribution of filamentous algae;
- continue the long-term assessment of the nutrient status of Gravenhurst Bay.

Despite their size and importance both as a recreational resource and to the regional economy, no routine monitoring programmes for any of these lakes existed before 1986.The only exception is Gravenhurst Bay on Lake Muskoka which had been sampled from 1969 to 1985 by O.M.E. (Phytoplankton Taxonomy Sect.). During the early 1970's, Gravenhurst Bay experienced periodic algae blooms associated with excessive nutrient inputs from the Gravenhurst Bay Sewage Treatment Plant (STP). (Dillon *et al*, 1978).

In 1971, the Gravenhurst STP became one of the first sewage treatment plants in Ontario to be equipped with phosphorus removal technology. This reduced greatly the amount of phosphorus entering Gravenhurst Bay. Due to problems with a second treatment plant in 1976, Gravenhurst Bay chlorophyll-a values reverted to pretreatment values. These problems were corrected in April 1976 and since then, except for 1980, a reduced steady state for phosphorus and chlorophyll-a has prevailed.

This report summarizes the water quality data collected from the 48 stations which were established on the four lakes in 1986. The data includes epilimnetic chemistry, euphotic zone chlorophyll and dissolved oxygen profiles.

METHODS

The location and number of the sampling sites on the four lakes Muskoka (13), Rosseau (12), Joseph (11), and Lake of Bays (12) includes both the embayments and the open areas of each lake (Tables 1, 2 and Figures 1-4, Appendix 1). One of the priorities of the programme is to sample the near shore areas and, therefore, embayments are sampled to a maximum depth of 20 m. The morphometry of each site (Tables 5-8, Appendix 1) was digitized from the maps of the Canadian Hydrographic Survey and volumetric estimates allowed sampling by volume-weighted methodology (Locke and Scott DR 86/4). Epilimnion depth was defined as the depth of thermal stratification (Wetzel, 1975). The euphotic zone, sampled for chlorophyll and phytoplankton, was defined as two times (2x) the secchi depth measurement.

Hypolimnetic oxygen depletion was assessed on the basis of a dissolved oxygen profile made from four depths at each station.

The exceptions are Gravenhurst (IM1) and Muskoka Bay (IM13) on Lake Muskoka and four stations on Lake of Bays; Trading Bay (IB2), Bigwin Is. (IB5), Dwight Bay (IB7), and Whiskey Bay (IB12). These basins are sampled at every odd metre from 1 m below the surface to the maximum depth.

Sampling occurred monthly throughout the ice-free season in each basin with the exception of Gravenhurst and Muskoka Bays on Lake Muskoka which were sampled bi-weekly. In addition to the volume-weighted sampling, a tube composite sample was collected. This produced continuity with data collected as unfiltered tube composites from 1972 to 1985 (Ken Nicholls, unpub. data) and allowed comparisons between the tube composite and volume-weighted sampling methods. The tube composite samples were collected by lowering a tygon tube (8 m by 2.5 cm) to a depth of 6 or 8 m (the euphotic zone). The tube was capped and the depth integrated sample thoroughly mixed in a carboy and then poured into the appropriate sampling containers for analysis. Unlike the volume-weighted samples, the tube composite samples are not filtered.

RESULTS

The chemistry summary of each basin (Appendix 2) and each lake (Table 3) are mean volume-weighted epilimnetic data for the period of June to October 1986. The chlorophyll data for each basin (Appendix 2) and each lake (Table 3 and 15) are euphotic zone ice-free 1986 mean values.

A. Nutrient Status of all Lakes

At present, the results show that with the exception of Muskoka and Gravenhurst Bay, the four lakes are representative of oligotrophic lakes in the Canadian Shield. Concentrations of total phosphorus and total Kjeldahl nitrogen ranged from 3.22 to 5.3 $\mu g \bullet L^{-1}$, and 170 - 210 $\mu g \bullet L^{-1}$ respectively, and chlorophyll-a levels are low 1.4 to 1.9 $\mu g \bullet L^{-1}$, (Table 3).

B. Nutrient Status of Gravenhurst Bay

In Muskoka and Gravenhurst Bays, levels of all nutrient status indicators are higher.

The data for phosphorus and chlorophyll levels exists from 1969 to 1986 (Table 3). In Gravenhurst Bay, the mean values of total phosphorus was 44 $\mu g \bullet L^{-1}$ and for chlorophyll was 9.8 $\mu g \bullet L^{-1}$ (Table 4), before the installation of the sewage treatment plant in 1971. Mean for phosphorus and chlorophyll-a from 1981 to 1986 is 12.9 $\mu g \bullet L^{-1}$ and 4.5 $\mu g \bullet L^{-1}$, respectively.

Table 3. A summary of 1986 epilimnetic chemistry for each of the study lakes. Values given are means and standard deviation of each parameter measured on each lake.

		Lake Joseph	Lake Rosseau	Lake of Bays	Muskoka including IM1 and IM13	Muskoka excluding IM1 and IM13

Table 4. The long-term Gravenhurst Bay Total Phosphorus and Chlorophyll-a Data (Dillon, 1978 and K. Nicholls, unpub. data).

	P ($\mu g \bullet L^{-1}$)	Chl-a
1969	42	10.6
1970	39	5.1
1971	52	13.8
1972	35	8.1
1973	33	6.9
1974	25	5.0
1975	20	5.0
1978	11.9	3.3
1979	12.7	3.6
1980	20.8	9.7
1981	15.7	3.5
1982	12.8	3.0
1983	16.0	6.1
1984	9.8	4.0
1985	11.3	5.2
1986	11.4	5.3

C. Sampling Site Comparisons

The selection of sampling sites included both the open lake areas and the embayments. When comparing the 1986 data from all of the stations in each lake, the between-station differences in chemistry are small (Note: S.D. data - Table 3). Therefore, a reduction in the number of sampling sites would not alter the integrity of a whole-lake data set. The stations eliminated for the 1987 sampling season include:

1. Lake Muskoka
   - IM2 - South Bay
   - IM5 - Walker's Pt. (Browing Is.)
   - IM7 - Bala Bay
   - IM9 - North Bay
   - IM10 - East Bay (Morris Is. - Rock Is.)
   - IM11 - Crown Is (Pudding Rock)

2. Lake Joseph
   - IJ2 - Hamer Bay
   - IJ4 - Yoho Island
   - IJ8 - Badgerow Is.
   - IJ10 - Black Forest Is.

3. Lake Rosseau
   - IR3 - Wiley's Bay
   - IR5 - Rest Harbour
   - IR6 - Tobin Is. (Ravenscrag Pt.)
   - IR11 - Venetia Group
   - IR12 - Mutchinbacher Bay

4. Lake of Bays
   - IB5 - Bigwin Is.
   - IB6 - Haystack Bay
   - IB9 - Seagull Rock
   - IB10 - Roothog Is. - Black Pt.

D. Dissolved Oxygen

The dissolved oxygen data (Appendix 3) are profiles from each basin. Ten stations have August and September dissolved oxygen data below 5 ppm in their hypolimnion, although only 3 became anoxic in 1986 - Gravenhurst Bay, Muskoka Bay (Lake Muskoka) and Pancake Bay (Lake of Bays).The other seven are small enclosed embayments. These stations were:

1. Lake Muskoka
   - Gravenhurst Bay
   - Pine Needle Pt. (Taylor Is.)
   - Dudley Bay
   - Muskoka Bay

   Lake Rosseau
   - Cameron Bay (at Rosseau)
   - Birch Is. - (East end) Skeleton Bay

   Lake Joseph
   - Little Lake Joseph
   - Chief's Island
   - Joseph River (Riverdale Is.)

   Lake of Bays
   - Pancake Bay

Each of these sites is a part of the 1987 sampling program.

E. Alkalinity - Lake of Bays

The Lake of Bays is classified as moderately sensitive (50-200 $\mu eq \bullet L^{-1}$) to acidic deposition. The t-test statistic ($p = 0.016$) indicates a significant difference between mean alkalinity measured in 1982 and 1986. The 1982 mean data is higher and can be explained by the two different sampling methods.

Lake of Bays was sampled at 9 sites on one occasion in July 1982. The epilimnetic alkalinity of 61.4 µeq●L^{-1} (DRC, unpub. data) was determined as the mean of all samples. The value for 1936 (70.9 µeq●L^{-1}) represents the mean of 5 observations made between June and October at 12 sampling sites.

F. Filamentous Algae (Zygnema, sp.)

The survey of these lakes in August 1986 (M. Jackson, pers. comm.) found the filamentous algae (*Zygnema*, sp.) in three basins only on the Lake of Bays. These bays, Pancake, Trading and Rabbit, are the most eastern three basins (Appendix 1, Figure 4). This is the first documentation of this algae species in the Lake of Bays. The algae is considered to be an early biotic indicator of acidification (Schindler *et al.* - 1985).

G. Sampling Method Comparisons

Gravenhurst Bay was sampled by both the volume-weighted and the tube composite methods. The tube composite samples were collected from 0-6 m or 0-8 m (the euphotic zone) and were not filtered. The comparable volume-weighted data were obtained from filtered, epilimnetic samples. The epilimnetic depth ranged from 0-4 to 0-6 m during the 1986 ice-free season. To determine if the volume-weighted samples are comparable to the 1986 tube composite data and, therefore, all previously collected samples, the data was analyzed both by regression (Table 5) and by a paired t-test (Table 6).

The comparison of the data with the paired t-test indicates that only F, NH_4, NO_3, and TP have significant differences in the means for the two types of data collection. For total phosphorus, ammonium and nitrate, the mean tube composite data is higher than the volume-weighted data. For each of these parameters, however, a highly significant ($p < 0.01$) regression indicates a strong relationship between values obtained by each sampling technique. For F, NO_3, and NH_4, the two methods are highly correlated ($r > 0.9$). Slopes of near unity and low values for the Standard Error of Estimation (S.E.E.) made by the regression indicate that between method

differences are small and correctable. For TP, a lower correlation (r = 0.7) and slope and a greater (S.E.E.), indicate consistent and large differences attributable to sampling techniques, which is shown as a higher mean value for the tube composite (Tc) samples. This bias only shows up for TP and may be partially explained by the fact that the Tc samples are unfiltered.

The linear regression data (Table 5) suggests that data collected by the two methods for Ca, DOC, Mg and pH are not consistently related. For each of these parameters, however, the t-test shows no significant difference in the mean values and the lack of a significant regression may only indicate that for each of these parameters, the data are scattered in a very narrow range.

Table 5. Gravenhurst Bay - volume-weighted epilimnion data and tube composite data: a test for linearity.

If $p<0.05$, there is a significant difference (ie. F, NH_4, NO_3, P)

CONCLUSIONS

The chemical data collected in 1986 indicate that the four lakes are oligotrophic with low nutrient and chlorophyll levels with the exception of specific embayments. Many of the stations within each lake are similar chemically. Therefore, a reduction in the number of basins sampled is planned.

The sampling of Gravenhurst and Muskoka Bays should continue because of the discharge of effluent into the lake from the Gravenhurst Sewage Treatment Plant has increased the nutrient levels.

Hypolimnetic depletion of dissolved oxygen was observed in only 10 of the 48 basins. Most of these 10 sites were small embayments and so anoxia was considered to be induced by the morphometric shape and depth of these embayments, and not by excess nutrient input.

All of the lakes were classified as moderately sensitive to acidic deposition on the basis of alkalinity measurements of 60-200 µeq/L.

Filamentous algae (*Zygnema*, sp.) appeared in three bays of the Lake of Bays in August 1986.

Comparison of volume weighted and tube composite methods of epilimnion sampling indicated only minor differences between the two methods, and so the volume weighted methodology was retained for future surveys.

The lakes can be characterized with fewer sampling locations. Therefore, 26 sampling sites were retained for further sampling in 1987 and 1988.
